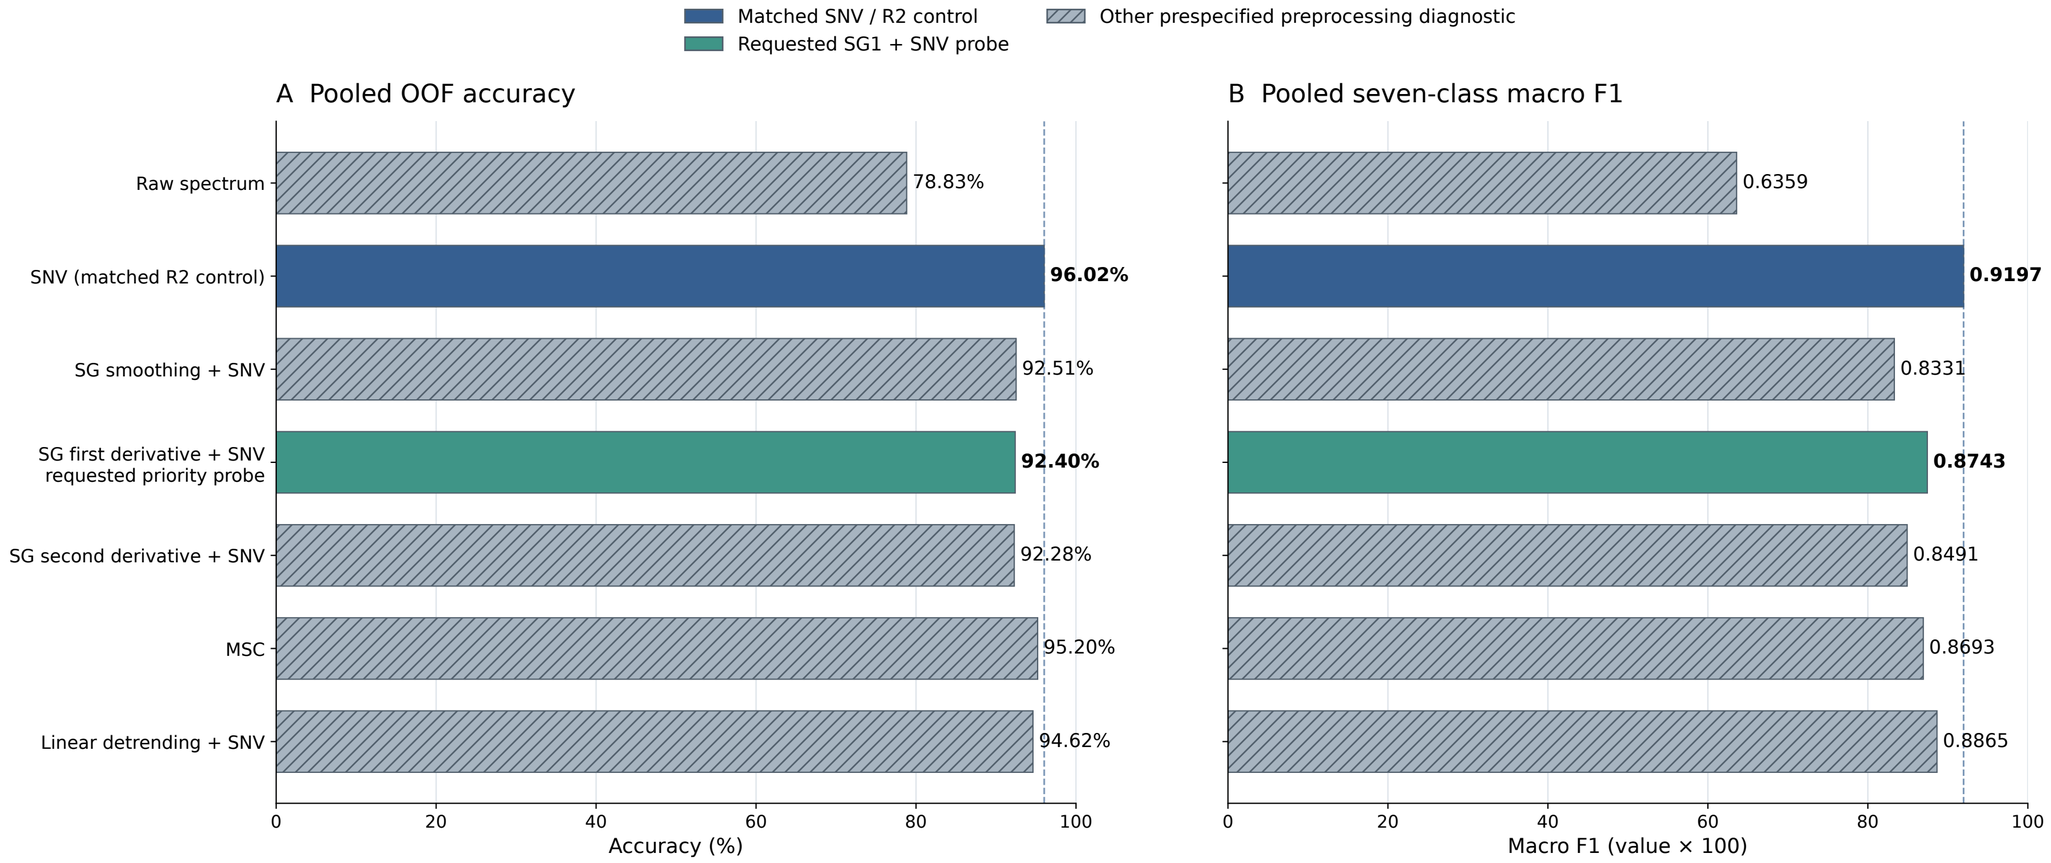
Preprocessing ablation under the same per-outer MC and SVM choices



SG1+SNV priority probe did not exceed SNV: accuracy 92.40% vs 96.02%; macro F1 0.8743 vs 0.9197.

These seven recipes were fixed before outer scoring. In every outer fold they share that fold's R1 MC and R2 SVM settings; source transforms/selectors are refitted.

SNV reproduces the R2 route. The formal R3 pipeline uses its own inner-selected recipe per outer fold; outer diagnostics are not used to overwrite that choice.

Each recipe uses standard SVC vote (break_ties=False), one OOF prediction per 855 specimens, matched 5 outer / 2 inner folds; pooled Macro F1.

Single-batch retrospective anonymous-group data; five folds are not independent batches. No CIs, no extrapolation to new batches or algorithm-novelty claim.

No comparison with earlier 171-sample holdout rankings. Dashed lines mark the matched SNV/R2 scores; both axes start at zero.
