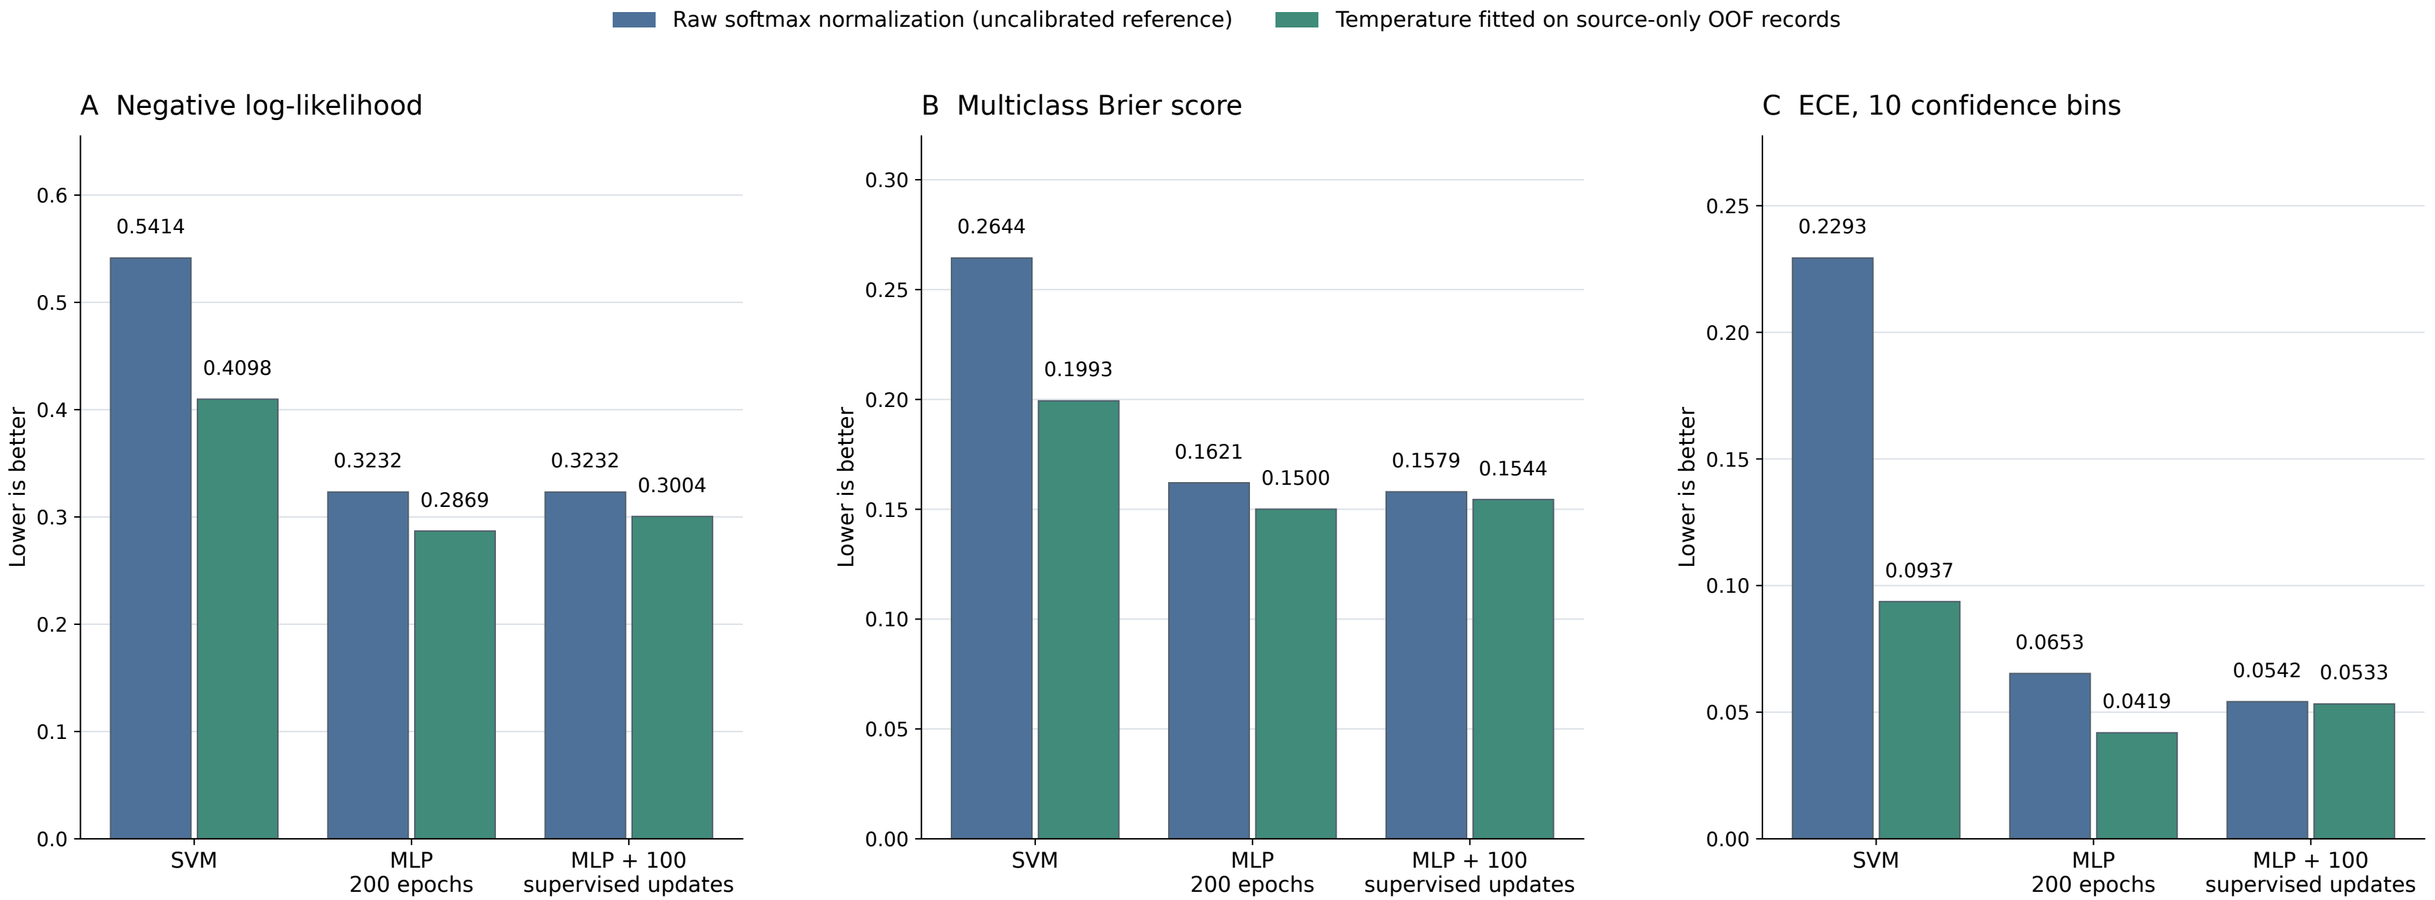
Source-OOF temperature scaling improves probability reliability, not class decisions



Positive temperature preserves argmax: accuracy and macro F1 are unchanged for each provider.

Unchanged accuracies — SVM: 88.89%, MLP: 89.08%, MLP+100: 90.25%. Formal fusion fallback has SVM weight 0; 90.25% is the single MLP source accuracy.

Raw softmax of SVM margins/MLP logits is a normalized reference, not a claim of an already calibrated posterior.

Brier is the sample mean of the sum of squared errors over all seven classes (not divided by seven). ECE uses ten equal-width bins.

Only source OOF labels fit temperatures; zero target-support labels and no query statistics are fitted.

Same 171 historical query specimens; three source-OOF seed contexts are not independent batches. Single-batch retrospective results; no CIs.
