
The selected LDA has higher accuracy (92.40%) but lower macro F1 (0.8352) than the previous MLP source (90.25%; 0.8787).

All plotted family candidates were selected in source-only development. Diagnostic final scores do not replace the locked selected model.

Counts average retained original frequencies across seeds; PCA-LDA uses 612 original inputs mapped to 40 source-fitted principal components.

Means of three recorded seeds (42/43/44), same 171 query specimens; one batch per group; retrospective analysis on historically used data.

No target-support labels, no independent new batches, no confidence intervals. Both horizontal axes start at zero.
